

Cologuard concerns

Convenience should not outweigh effectiveness and accuracy. Up to 45% of Cologuard screenings are False Positive and may require a more precise Colonoscopy. A positive or false positive Cologuard screening can result in an additional Colonoscopy screening to determine if there are cancerous polyps.

Up to
45%

of Cologuard screenings are false positives and may require a more precise Colonoscopy.

Many Insurance benefit plans only fully cover one colorectal cancer screening. Patients can be hit with a high “out of pocket” cost if a second, follow-up test is required.

Roughly

1 in 13

Cologuard screenings failed to detect colorectal cancer.

A Colonoscopy Screening is the *only* test has the ability to remove and test polyps to determine if they are cancerous.

When to start screening

**AGE
45**

New guidelines recommend that most patients get their initial screening at age 45. African Americans and people with a family history of cancer should get an earlier screening. Talk to your doctor about the best screening schedule for you.

The bottom line: Colonoscopy is the most effective test for colorectal cancer.

Any colorectal cancer screening is better than none at all, but a Colonoscopy is the most accurate and effective test for detecting and preventing colorectal cancer.
